

OCT 30 2008

Application Serial. No.: 10/586,562
Attorney Docket No.: 26281-23A

Examiner: J. Goodrow
Art Unit: 1795

AMENDMENTS TO THE CLAIMS

1. (Currently amended) A toner for electrostatic latent image development which contains at least toner particles and inorganic particles and which is used for an image forming apparatus providing a corona charging instrument, wherein

the toner particles exhibit a shape factor SF-1 which satisfies the relationship about $115 \leq \text{SF-1} \leq 150$ and a shape factor SF-2 which satisfies the relationship about $115 \leq \text{SF-2} \leq 145$ and, at the same time, a quantity of inorganic particles which are not adhered to the toner particles and are in a floating state and which is measured by using a microwave induced plasma emission spectrophotometry method, is set to a value which falls within a range from about 10 weight% to 25 weight% with respect to a total quantity of the inorganic particles.

2. (Original) The toner for electrostatic latent image development according to claim 1 wherein the inorganic particles are formed of grinding particles.

3. (Previously presented) The toner for electrostatic latent image development according to claim 1 wherein the inorganic particles are formed of at least one selected from a group consisting of alumina, titanium oxide, magnesium oxide, zinc oxide, strontium titanate and barium titanate.

4. (Currently amended)) The toner for electrostatic latent image development according to claim 1 wherein a total an-adding quantity of the inorganic particles is set to a value which falls within a range from about 0.1 to 10 parts by weight with respect to 100 parts by weight of the toner particles.

5. (Canceled)

6. (Previously presented) The toner for electrostatic latent image development according to claim 1, wherein the toner is formed of a magnetic monocomponent toner.

7. (Currently amended) A method of magnetic monocomponent development which is used for an image forming apparatus providing a corona charging instrument and which forms a predetermined toner image by forming an electrostatic latent image on a photoconductor and developing the electrostatic latent image with a magnetic monocomponent developing toner by using a developing sleeve, wherein

the method uses the magnetic monocomponent developing toner in which toner particles exhibit a shape factor SF-1 which satisfies the relationship about $115 \leq SF-1 \leq 150$ and a shape factor SF-2 which satisfies the relationship about $115 \leq SF-2 \leq 145$ and, at the same time, a quantity of inorganic particles which are not adhered to the toner particles and are in a floating state and which is measured by using a microwave induced plasma emission spectrophotometry method, is set to a value which falls within a range from about 10 weight% to 25 weight% with respect to a total quantity of the inorganic particles.

8. (Original) The method of magnetic monocomponent development according to claim 7, wherein the surface roughness (Rz) of the developing sleeve is set to a value which falls within a range from about $3.0\mu\text{m}$ to $5.5\mu\text{m}$.

9. (Original) The method of magnetic monocomponent development according to claim 7, wherein the photoconductor is an amorphous-silicon photoconductor.
